

QA Automation Assignment Documentation

Overview

This assignment focused on web application testing, workflow automation using n8n, API integration, monitoring, and error handling. The tasks were completed using the RealWorld demo application, public APIs, and Discord webhook integration.

Task 1 — Web App QA Testing

The RealWorld demo application was tested by validating important user workflows including signup, login, article creation, editing, deletion, and logout. Multiple issues were identified during testing, including validation problems, unclear error handling, response inconsistencies, and usability issues. The findings were documented in a QA report along with reproduction steps, severity, expected behavior, and actual behavior. A short root-cause analysis was also completed for one identified issue.

Task 2 — n8n API Integration Workflow

An automated n8n workflow was created to fetch live API data, transform and filter the response, enrich selected results using another API request, and send notifications through a Discord webhook. Conditional logic using IF nodes was implemented to route responses based on thresholds. Retry handling and Continue On Fail options were configured to prevent silent workflow failures.

Bonus Task — Uptime Monitoring Workflow

A second workflow was developed to monitor application uptime every 5 minutes. The workflow checks the application's HTTP status code and automatically sends a Discord alert if the response is anything other than 200. Full response handling and retry logic were enabled to improve reliability.

Technologies Used

- n8n
- Discord Webhooks
- HTTP APIs
- GitHub
- VS Code
